Post-Goal Control: Executive Summary

38

PL matches

962

shots

108

goal events

5 / 10 / 15

min windows

Question

What allows Newcastle to retain control after scoring, and why does that control weaken - particularly away from home?

Four findings that matter

1 Shot quality, not just volume - 15 minutes after scoring: +0.160 xG and +0.190 SOT differential. Newcastle shots averaged 0.170 xG vs 0.090 for opponents, were closer (13.8m vs 15.8m) and more often inside the box (74.4% vs 66.2%).

2 The away-game drop is clear - After scoring: home PGCI 55.6 and +0.217 xG; away PGCI 45.8 and +0.067 xG. The post-score pressure signal fell from +9.16 at home to +2.79 away.

3 Territory is the strongest mechanism - Positive post-score pressure: PGCI 62.4, +0.314 xG, +0.519 SOT. Negative pressure: PGCI 32.9, -0.118 xG, -0.400 SOT.

4 Personnel gives video-review targets - Schär and Miley repeatedly feature in high-control windows. Miley + Tonali: PGCI 80.3 across 8 qualifying windows (+0.524 xG; +1.50 SOT) - an association to review, not a causal ranking.

Football implication

The actionable question is not simply how Newcastle take more shots after scoring. The evidence points toward retaining territory and chance quality after going ahead. Video review should test repeatable behaviours in midfield spacing, counter-press positioning, second-ball control, full-back height and progression after regains - especially away from home.

Method & credibility

Event-level PL analysis with added-time-adjusted windows; shots, SOT, xG/xGOT, locations, venue, game state, territorial pressure and player-unit splits. **PGCI** = Newcastle mean share of shots, SOT and xG (50 = even). Results are descriptive associations, not causal claims; small player/pair samples are video-review leads.
